Abstract

This study constructs a Multidimensional Financial Vulnerability Index (MFVI) for Indian women aged 15–49 using NFHS-5 data (2019–21) covering 724,115 eligible women across 36 states. The MFVI follows the Alkire-Foster dual-cutoff method across five equally weighted dimensions: formal account access, digital finance, asset ownership, formal credit, and savings behaviour. Principal Component Analysis validates the index ($r = 0.77$ with equal-weight version). The complete-case sample of 30,226 women yields a mean AF score of 0.483 (deprivation in ≈ 2.4 dimensions on average); under a two-dimension cutoff, 83.2% are jointly financially vulnerable. Savings deprivation is most prevalent.

Empirical methods include OLS with state fixed effects, a Linear Probability Model, quantile regression (10th, 50th, 90th percentiles), Oaxaca-Blinder decomposition, domain-specific regressions, and intergenerational analysis. Rural residence and Scheduled Caste/Tribe membership are the strongest predictors of higher vulnerability. Limited media exposure increases vulnerability, whereas employment reduces the AF score by 0.024 points and vulnerability probability by 3 percentage points. Education is non-monotonic: primary/secondary education raise AF scores (a measurement artefact of greater formal system engagement), but higher education significantly reduces vulnerability (coefficient -0.0207). Wealth quintile effects are similarly non-monotonic. Quantile regression shows protective effects are strongest for the most vulnerable women (90th percentile). Intergenerational analysis links maternal vulnerability to higher child mortality (coefficient 0.082) and son preference (coefficient 0.021). Policy must shift from nominal to substantive financial inclusion, targeting rural digital infrastructure, caste-sensitive products, quality employment, and higher education.

Keywords: Multidimensional deprivation; financial inclusion; gender; India; NFHS-5; intergenerational transmission.

1. Introduction

1.1 Background

“Nothing, arguably, is as important today in the political economy of development as an adequate recognition of women’s political, economic, and social participation.”

~Amartya Sen

Financial Vulnerability is defined as a state of being deprived of basic rights to access monetary resources or to be denied of the authority over it. Indian economy has seen robust development over the decades. From liberalisation in late 20th century to marching towards self-sufficient economy by 2047, Indian economy has truly exhibited stable growth amongst its counterparts. However, this has had very little impact in financially empowering women of the country. This can be attributed to various reasons spanning from complex social structure, inherent patriarchal household, to denial of basic rights such as education, lack of equal opportunities and fundamental security issues.

These systemic limitations in the overall development of women have had impetuous impacts in the economic development of the country. As women constitute about 50% of the population, limiting their growth can have direct reflections on socio-economic dynamics. This has widened the inequality gap between men and women in India.

Thus, this project intends to study the effects of various socio-economic factors such as education, wealth, access to credit, marital status, media exposure on financial vulnerability of women. While various measures have been taken by the government of India through schemes like “Sukanya Samridhi Yojana”, “Mahila Saman savings certificate”, “ladli behen yojana” etc to financially empower women, these indices aim to help in understanding the traces of vulnerabilities that are often overshadowed by concerns like harassment, domestic violence, and other social evils. However, it is important to analyse other factors as mentioned earlier to arrive at a holistic understanding of the problem. This helps the government not just in formulating better policies, but also in spotting the real areas of concern, catering to proper execution of the policies.

1.2 Problem Statement

Financial vulnerability among women in India is inherently multidimensional, shaped by socio-economic constraints, structural inequalities, and uneven access to financial resources.

Conventional measures based on income or account ownership fail to capture this complexity, overlooking critical dimensions such as digital literacy, credit access, asset ownership, and intra-household decision-making power.

The absence of an integrated framework limits a full understanding of both the determinants and consequences of financial vulnerability, including its intergenerational effects. This study seeks to address this gap by developing a multidimensional approach that captures these intersecting factors, as illustrated throughout the paper.

1.3 Research Objectives

This study aims to address four objectives. First, to construct a multidimensional financial vulnerability index using the Alkire-Foster method and validate it against a PCA derived alternative. Second, to identify the socioeconomic determinants of financial vulnerability using OLS, LPM, and Quantile Regression. Third, to analyse the distributional patterns of vulnerability across wealth quintiles, education levels, social groups, and Indian states. Fourth, to examine whether financial vulnerability is associated with worse intergenerational outcomes: specifically, child mortality and son preference.

1.4 Research Questions

- (i) What is the incidence and distribution of multidimensional financial vulnerability among women aged 15–49 in India?
- (ii) Which socioeconomic characteristics are the strongest predictors of financial vulnerability?
- (iii) Does the protective effect of education differ between urban and rural women?
- (iv) Is current financial vulnerability associated with worse child survival outcomes?

1.5 Scope of the Study

The study uses the NFHS-5 Individual Recode (IAIR7EFL.DTA), covering 724,115 eligible women across all 36 Indian states and union territories. Regression analyses use a complete-case sample of 30,226 observations. All analyses are conducted in Stata 17.

1.6 Structure of the Paper

Following this, Section 2 reviews the relevant literature. Section 3 describes the data and methodology. Section 4 presents results and discussion with full regression outputs. Section 5 sets

out policy implications. Section 6 acknowledges limitations. Section 7 concludes. Tables and figures follow the references in Section 9.

2.Literature Review

2.1 Conceptualizing Vulnerability: From Unidimensional to Multidimensional Frameworks

The understanding of vulnerability has evolved considerably over the past several decades from the narrow, hazard-focused definitions to comprehensive and multidimensional frameworks. Early researchers focused mainly on exposure to natural disasters, largely ignoring the social, political, and economic conditions that make certain groups more fragile than others. (Gunaratne et al., 2023). By the 1980s, scholars began to recognise that the real roots of vulnerability lie in broken or unequal systems and not just in external shocks (Gunaratne et al., 2023).

Today, vulnerability is understood as something that is complex, context-specific, and always changing. Despite this, much empirical research still measures it in one dimension at a time. Gallardo (2020) addresses this by formally extending risk measurement into a multidimensional space through a Vulnerability to Multidimensional Poverty Index (VMPI), which combines risk analysis with the widely used Alkire-Foster counting framework. Meanwhile, Abraham and Kavi Kumar (2008) draw a useful distinction in the Indian context: poverty tells us where someone stands today, while vulnerability tells us where they are likely to end up. This matters enormously as households that are not yet poor but are structurally at risk are routinely missed by policy.

Within financial vulnerability specifically, Salignac et al. (2019) argue that resilience, which is the opposite of vulnerability- is made up of economic resources, financial products, financial knowledge, and social networks. Kumar and Singh (2025) and Coban and Salti (2024) both draw on Amartya Sen's Capability Approach, arguing that vulnerability is fundamentally about being deprived of the capabilities needed to live securely and not just about having a low income. The shared conclusion across all these perspectives is clear: single-indicator measures simply cannot capture the reality of overlapping disadvantages.

2.2 Measuring Multidimensional Vulnerability: Tools and Frameworks

Various research tools have been employed to operationalize multidimensional vulnerability. Gunaratne et al. (2023) review frameworks such as the MOVE Framework and the 360° Integrated Assessment Map, both of which treat vulnerability as shaped by economic, institutional, and

cultural forces and not as something shaped by just physical exposure. At the regional level, Ram et al. (2019) built a Multidimensional Vulnerability Index tailored to the Caribbean, accounting for specific pressures like export dependency and extreme weather. Srivastava (2024) makes the case for folding conflict vulnerability into a global index, arguing that this is essential for directing long-term resilience financing toward the most structurally disadvantaged nations.

Abraham and Kavi Kumar (2008) used a fuzzy logic approach to rank Indian states by vulnerability, revealing that an absence of income poverty does not guarantee freedom from other deprivations. At a broader level, the Alkire-Foster method has proven particularly useful for capturing concurrent disadvantages across dimensions like health, education, and financial security; illustrated by Coban and Salti's (2024) study of Syrian refugee and Lebanese households. Building on these methods, Kumar and Singh (2025) constructed a Financial Vulnerability Index (FVI) for older adults in India, while Salignac et al. (2019) found that individuals facing multiple overlapping disadvantages tend to cluster at the most severe end of the risk spectrum. This confirms that vulnerability compounds rather than simply adding up.

2.3 Gender and Financial Vulnerability

Across the literature, gender emerges as one of the most consistent and structurally embedded drivers of financial vulnerability. Women face higher levels of financial deprivation at nearly every stage of life, shaped by unequal access to labour markets, property rights, and social protection. In India, Kumar and Singh (2025) show that being a woman significantly increases financial vulnerability among older adults, a gap made worse by widowhood which combines interrupted earnings with rigid inheritance norms.

Importantly, this vulnerability is not confined to poor households. Roy (2021) argues that economic vulnerability in India is a deeply patriarchal phenomenon that cuts across class lines. India's low ranking on the Women, Peace, and Security Index reflects the fact that even women in relatively wealthy households often lack genuine financial independence. In conflict-affected settings, Coban and Salti (2024) found that the multidimensional poverty rate for female-headed Lebanese households exceeded 50%, compared to just 10% for male-headed ones. Though Salignac et al. (2019) found that average resilience scores in Australia did not differ sharply by

gender, the underlying picture told a different story: men tended to have more economic resources and financial knowledge, while women depended more heavily on social networks.

As Coban and Salti (2024) note, these vulnerabilities can only be understood through an intersectional lens. In India particularly, the full picture requires accounting for gender alongside caste, class, and geography.

2.4 Structural Drivers: Education, Caste, Location, and Social Protection

Beyond gender, the literature identifies education, caste, geographic residence, and access to formal social protection as the primary structural determinants of financial vulnerability. Kumar and Singh (2025) find that the absence of formal education is the single most powerful sociodemographic risk factor for late-life vulnerability in India, followed by living in a rural area and belonging to a Scheduled Caste or Scheduled Tribe community.

A critical finding in the literature is that simply having access to financial systems is not the same as being protected by them. Kumar (2017) observes that while most tribal households in rural Kerala now hold bank accounts- largely through government labour programs, account ownership alone has done little to reduce financial insecurity. Similarly, Guérin et al. (2009) argue that rural microfinance schemes in South India frequently fail because they treat rural communities as uniform, overlooking the irregular nature of rural incomes and the role of caste in shaping who benefits.

On the other hand, the absence of pension and insurance coverage remains a reliable marker of severe vulnerability (Kumar & Singh, 2025; Coban & Salti, 2024). Digital Financial Inclusion (DFI) is also emerging as a meaningful structural intervention. Wang and Mao (2023) show that digital financial tools help older populations manage assets better and reduce economic dependence, while Álvarez-Espino et al. (2025) find that diverse digital payment methods reduce both objective and subjective financial vulnerability, helping to close longstanding geographic gaps.

2.5 Resilience and the Quality of Financial Inclusion

An asset-based perspective frames financial vulnerability not merely as a culmination of deficits, but through the lens of financial resilience- the capacity to leverage internal and external resources

to withstand economic shocks. Salignac et al. (2019) describe this as the active interplay of economic resources, suitable financial products, financial knowledge, and social networks. However, the literature is clear that financial inclusion is only meaningful when it is substantive. Chipunza and Fanta (2023) find that basic financial inclusion disproportionately benefits the wealthiest fifth of those included, leaving the most marginalised behind. Bukari et al. (2023) add that informal financial markets are in fact vital safety nets, particularly for women navigating daily economic pressures.

Salignac et al.'s (2019) scenario analysis illustrates powerfully how overlapping disadvantages such as being female, underemployed, and low-income simultaneously produce vulnerability that is exponentially greater than any single factor would suggest. This directly supports both Gunaratne et al.'s (2023) call for multidimensional frameworks and Abraham and Kavi Kumar's (2008) argument that narrow, dimension-specific interventions are insufficient for building lasting resilience.

2.6 The Forward-Looking Case for Vulnerability Measurement

A defining, yet historically underutilized, contribution of vulnerability literature is its predictive utility. Abraham and Kavi Kumar (2008) state that while poverty measures audit present failures, vulnerability indices map future risks, allowing for pre-emptive policy intervention among households that are currently not poor but structurally fragile.

This temporal logic is invaluable for analysing women's financial trajectories in India. Women who currently exist above the poverty line but exhibit structural risk factors such as rural residence, lack of education, informal employment, and patriarchal financial dependence (Roy, 2021) constitute a critical target demographic. Without intervention, these risk factors tend to compound across the life course, often resulting in severe deprivation later, particularly following events such as widowhood. As Salignac et al. (2019) note- resilience is not a fixed state; tracking how vulnerabilities evolve over time and across generations is essential to understanding the full picture.

2.7 Measurement Approaches and Research Gaps

There is now strong consensus in literature that composite, multidimensional tools are necessary to capture the compounding nature of socio-economic risk (Gunaratne et al., 2023; Gallardo, 2020;

Srivastava, 2024). Studies consistently show that multidimensional vulnerability rankings diverge significantly from income-based measures, successfully capturing deprivations linked to patriarchal structures, asset deficits, and social marginalisation (Abraham & Kavi Kumar, 2008; Kumar & Singh, 2025; Roy, 2021).

Despite the progress, gaps however still persist in understanding financial vulnerability among Indian women. While the gendered aspects of late-life financial vulnerability are well documented (Kumar & Singh, 2025), there is limited insight into how this vulnerability develops across age cohorts or is transmitted between generations. Although digital financial inclusion (Wang & Mao, 2023) and access to high-quality financial services (Chipunza & Fanta, 2023; Bukari et al., 2023) are recognized as protective factors, their effectiveness within India's complex social structure shaped by class hierarchies (Roy, 2021) and rural caste dynamics (Guérin et al., 2009; Kumar, 2017) remains insufficiently examined. Additionally, no study has yet integrated vulnerability prediction, a multidimensional resilience framework, and an intersectional gender lens to provide a cohesive intergenerational assessment of financial vulnerability among Indian women.

3. Data and Methodology

3.1 Data Source and Sampling Design

This study uses individual-level microdata from the fifth round of India's National Family Health Survey (NFHS-5), conducted between 2019 and 2021 across all 36 states and union territories. The NFHS-5 is implemented by the International Institute for Population Sciences (IIPS) under the Ministry of Health and Family Welfare, Government of India, and is designed as a stratified two-stage cluster probability sample (IIPS and ICF, 2021). The Individual Recode file (IAIR7EFL.DTA) provides one observation per eligible woman aged 15–49 years, containing detailed information on household assets, financial behaviours, anthropometric outcomes, and a wide range of socioeconomic characteristics. The raw dataset contains 724,115 women.

The sampling design employs probability-proportional-to-size (PPS) selection at the primary stage, where primary sampling units (clusters) are identified by the variable v001. Sampling weights (v005) and stratification identifiers (v022) enable nationally representative inference when correctly declared. In this study, the complex survey design is declared in Stata as:

```
svyset v001 [pweight=v005], strata(v022) singleunit(centered)
```

This declaration enables variance estimation that correctly accounts for clustering and stratification. A survey-weighted OLS is estimated alongside the primary unweighted specification as a robustness check (Table B, Appendix). For main regression analyses, the complete-case analytic sample is 30,226 observations — determined by the joint availability of all five AF index variables and the main regression control variables. The sample reduction is documented in the attrition table (Table 6).

3.2 Variable Construction

3.2.1 Choice of Variables for Various Models

The analysis draws on a set of variables from the NFHS-5 individual recode, organised into four functional groups as summarised in the table below. The AF Index Dimensions (s931, s933, v745b, s941, v170) form the core of the multidimensional financial vulnerability measure, each capturing a distinct aspect of financial inclusion or deprivation. Intergenerational Variables (v201, v218, v202) are used to construct the child mortality rate and son preference index, which serve as outcome variables for the intergenerational analysis. Regression Controls include demographic and socioeconomic characteristics (education, wealth, residence, age, employment, marital status, media exposure, household size) that are standard in the literature on women's economic outcomes and are included in all multivariate models to reduce omitted variable bias. Finally, Survey Design Variables (v001, v005, v022) are used to declare the complex sampling design and to compute nationally representative standard errors.

Table: Variables Used in the Research

Variable Name	Variable	Description
AF Index Dimensions		
Financial Access	s931	Woman has a bank or savings account in her own name (0 = no, 1 = yes)
Digital Finance	s933	Woman uses mobile phone for financial transactions (0 = no, 1 = yes)
Asset Ownership	v745b	Woman owns land or immovable assets alone or jointly (0 = no, 1 = yes)
Credit Access	s941	Woman has ever taken a loan from a formal source (0 = no, 1 = yes)
Savings Behaviour	v170	Woman has and actively uses a savings account (1 = yes, other = no)

Variable Name	Variable	Description
Intergenerational Variables		
Children ever born	v201	Total number of live births the woman has had
Living children	v218	Number of children currently alive
Living sons	v202	Number of living sons (used for son preference index)
Regression Controls		
Education level	v106	Highest educational level (0 = no education, 1 = primary, 2 = secondary, 3 = higher)
Wealth quintile	v190	Household wealth index (1 = poorest, 2 = poorer, 3 = middle, 4 = richer, 5 = richest)
Place of residence	v025	Type of residence (0 = urban, 1 = rural)
Age	v012	Respondent's current age in years
Age squared	age_sq	Derived as v012 ² to capture non-linear age effects
Employment status	v714	Currently working (0 = no, 1 = yes)
Marital status	v502	Current marital status (never married, currently married, widowed/ divorced/ separated)
Newspaper reading	v157	Frequency of reading newspaper (0 = not at all, 1 = less than once a week, 2 = at least once a week, 3 = almost every day) and missing recoded to 0
Radio listening	v158	Frequency of listening to radio (same coding as above)
T/V watching	v159	Frequency of watching television (same coding as above)
Household size	v136	Number of usual members in the household
Supplementary Variables (Social Group)		
Caste	s116	Caste classification (1 = Scheduled Caste, 2 = Scheduled Tribe, 3 = Other Backward Class, 4 = None/General)
Religion	v130	Religion (1 = Hindu, 2 = Muslim, 3 = Christian, 4 = Sikh, etc.)
State	v024	State/union territory code (36 categories; used as fixed effects)

Variable Name	Variable	Description
Survey Design Variables		
Cluster	v001	Primary sampling unit (cluster) for variance estimation
Sampling weight	v005	Women's individual sample weight (6 decimals)
Stratum	v022	Sample strata for sampling errors

3.2.2 Data Cleaning Protocol

All analysis variables are cleaned prior to index construction. Survey non-response codes value 9 for single-digit coded variables and value 99 for double-digit coded variables are recoded to system missing (.) using Stata's replace command within a foreach loop across all relevant variables. This applies to the five AF index variables (s931, s933, v745b, s941, v170), intergenerational variables (v201, v218, v202), and all regression control variables (v106, v190, v025, v012, v714, v502, v157, v158, v159, v136). Supplementary variables (s116, v130, v131, v024, v151, v133) are cleaned with a capture prefix to suppress errors when variables are absent from a specific state recode file. Newspaper reading frequency (v157) is separately recoded to zero for missing observations under the assumption that missingness reflects non-exposure rather than non-response; this is a standard convention in media exposure modelling with DHS data.

3.2.3 Alkire-Foster Multidimensional Vulnerability Index

The primary measure of financial vulnerability is constructed using the Alkire-Foster (AF) dual-cutoff method (Alkire and Foster, 2011). The AF method is selected for three reasons. First, it satisfies a set of axioms that single-indicator measures do not: it captures both the incidence of deprivation (who is deprived) and the intensity of deprivation (in how many dimensions simultaneously). Second, it is consistent with the capability approach's emphasis on the joint distribution of achievements across multiple functionings (Sen, 1999). Third, it permits decomposition by dimension and population subgroup, which is essential for the domain-specific and social group analyses in this study.

Five dimensions of financial vulnerability are operationalised as binary deprivation indicators ($d_j \in \{0, 1\}$, where 1 = deprived, 0 = not deprived):

- Financial Access (*dep_fin*): s931 = 0. Absence of a formal bank account in the woman's own name. This is the foundational indicator of formal financial inclusion (Demirgüç-Kunt et al., 2018).
- Digital Finance (*dep_digital*): s933 = 0. Non-use of mobile payment or mobile banking services. This captures the technological dimension of financial access, directly relevant to India's digital payment agenda.
- Asset Deprivation (*dep_asset*): v745b = 0. Absence of land or immovable asset ownership in the woman's name. Asset ownership provides economic security, collateral access, and intergenerational wealth transfer (Doss, 2013).
- Credit Deprivation (*dep_credit*): s941 = 0. Absence of any formal credit facility. Formal credit access is essential for entrepreneurship and consumption smoothing in the face of income shocks.
- Savings Deprivation (*dep_savings*): v170 ≠ 1. Absence of an actively used personal savings account encompassing both women with no account and those whose account is controlled exclusively by another household member. This is the broadest savings measure available in NFHS-5.

Each dimension receives an equal weight $w_j = 0.20$. The composite deprivation score for woman “i” is computed as:

$$c_i = \sum_{j=1}^5 w_j \times d_{ij} \text{ where } w_j = 0.20 \text{ and } d_{ij} \in \{0,1\}$$

A woman is classified as financially vulnerable if $c_i \geq 0.33$ — that is, if she is simultaneously deprived in at least two of the five dimensions (since $2 \times 0.20 = 0.40 > 0.33$, this implements the dual cutoff at the two-dimension threshold). The dual-cutoff approach distinguishes the AF method from simple count measures and ensures vulnerability identification is sensitive to joint deprivation rather than marginal deprivation in a single dimension.

3.2.4 PCA Validation Index

Principal Component Analysis (PCA) is applied to the standardised (z-scored) values of the five binary deprivation variables to provide a data-driven alternative weighting scheme. Prior to PCA, each variable is standardised to mean zero and unit standard deviation using Stata's `egen std()` function. The PCA is then estimated on the five standardised variables ($z_s931, z_s933, z_v745b, z_s941, z_v170$).

The first principal component (PC1, eigenvalue = 2.03) is retained on the Kaiser criterion (eigenvalue > 1) and accounts for 40.65% of total variance. PC2 accounts for a further 21.26%; subsequent components fall below 20% individually. The Kaiser rule thus justifies retaining PC1 as the sole PCA-based index. PC1 scores are extracted using Stata's predict command and standardised to mean 0, standard deviation 1 to produce the *pca_index*. A PCA-weighted AF index (*c_score_pca*) is constructed using the absolute values of PC1 loadings normalised to sum to one as alternative dimension weights:

$$nw_j = |\lambda_j| / \sum |\lambda_j| \text{ where } \lambda_j \text{ is the PC1 loading on dimension "j"}$$

The largest PC1 loadings are on financial access ($z_s931 = 0.6956$) and savings ($z_v170 = 0.6956$), which load identically, reflecting their almost same empirical correlation. The correlation between *c_score* and *c_score_pca* is 0.77 in the analytic sample, indicating that weighting choices moderately influence vulnerability rankings but remain substantially aligned.

3.2.5 Social Group Variable

A six-category social group variable is constructed by combining the NFHS-5 caste classification (s116: Scheduled Caste = 1, Scheduled Tribe = 2, Other Backward Class = 3, None/General = 4) with religion (v130: Hindu = 1, Muslim = 2, other religions > 2). The categories are: (1) Scheduled Castes, (2) Scheduled Tribes, (3) Other Backward Classes, (4) Hindu General, (5) Muslim General, and (6) Other Minorities. This variable captures the intersection of caste-based structural disadvantage and religious minority status, both recognised as independent drivers of economic marginalisation in India (Roy, 2021; Guérin et al., 2009).

3.2.6 Control Variables and Age Specification

Regression models include the following controls: education level (v106: 0 = no education, 1 = primary, 2 = secondary, 3 = higher, entered as categorical dummies); household wealth quintile (v190: 1 = poorest to 5 = richest, categorical); place of residence (v025: 0 = urban, 1 = rural); current age in years (v012, continuous); age squared (v012², created as $\text{age_sq} = \text{v012}^2$) to capture non-linear life-cycle effects in financial participation; employment status (v714: binary, 1 = currently employed); marital status (v502: categorical); newspaper reading frequency (v157); radio listening frequency (v158); television watching frequency (v159); household size (v136); and state of residence as fixed effects (v024, 36 categories). State fixed effects absorb all time-

invariant unobserved state-level heterogeneity including state-level financial infrastructure, regulation, and cultural norms that would otherwise confound the estimated coefficients.

3.3 Empirical Strategy

3.3.1 OLS Regression on the Continuous AF Score

The primary regression model estimates the linear relationship between socioeconomic characteristics and the continuous AF vulnerability score. The structural form of the OLS equation is:

$$c_score_i = \beta_0 + \beta_1 Educ_i + \beta_2 Wealth_i + \beta_3 Rural_i + \beta_4 Age_i + \beta_5 Age_i^2 + \beta_6 Work_i + \beta_7 Marital_i + \beta_8 Newspaper_i + \beta_9 Radio_i + \beta_{10} TV_i + \beta_{11} HHSIZE_i + \sum \gamma_s \cdot State_{si} + e_i$$

where β_0 is the intercept; β_1 through β_{11} are vectors or scalars of partial regression coefficients; $Educ_i$ is a categorical education variable (primary, secondary, higher relative to no education); $Wealth_i$ is a categorical wealth quintile (quintiles 2–5 relative to poorest); $Rural_i$ is a binary indicator (1 = rural); Age_i and Age_i^2 jointly capture the non-linear life-cycle profile; $Work_i$ is binary employment status; $Marital_i$ is marital status; $Newspaper_i$, $Radio_i$, and TV_i capture media exposure frequency; $HHSIZE_i$ is household size; $\sum \gamma_s \cdot State_{si}$ is the vector of 35 state fixed-effects dummy variables (with one state as reference); and e_i is the idiosyncratic error term.

Before estimation, a Breusch-Pagan (1979) Lagrange Multiplier test is conducted under the null hypothesis of homoskedastic errors. Given a statistically significant result, all OLS models are estimated with heteroskedasticity-robust standard errors (the Huber-White sandwich estimator), which are consistent even when the error variance is non-constant across observations. Variance Inflation Factors (VIFs) are computed to verify the absence of serious multicollinearity.

3.3.2 Linear Probability Model (LPM)

A Linear Probability Model is estimated with the binary vulnerability indicator ($vulnerable_i \in \{0, 1\}$), defined as $c_score_i \geq 0.33$) as the dependent variable:

$$P(vulnerable_i = 1) = \beta_0 + \beta_1 Educ_i + \beta_2 Wealth_i + \beta_3 Rural_i + \beta_4 Age_i + \beta_5 Age_i^2 + \beta_6 Work_i + \beta_7 Marital_i + \beta_8 Media_i + \beta_9 HHSIZE_i + \sum \gamma_s \cdot State_{si} + e_i$$

LPM coefficients are interpreted as marginal changes in the probability of being classified as financially vulnerable associated with a unit change in each covariate, holding all other covariates constant. The LPM is preferred over probit or logit in this context because of its interpretability in large samples, the ease of incorporating state fixed effects, and the consistency with practice in the multidimensional poverty literature. Predicted probabilities from the LPM are summarised to verify that fitted values do not substantially exceed the $[0, 1]$ interval. Robust standard errors are applied throughout.

3.3.3 Quantile Regression

Quantile regression (Koenker and Bassett, 1978) is estimated at the 10th, 50th, and 90th percentiles of the AF score distribution, using the same covariate set as the primary OLS. While OLS estimates the conditional mean $E[c_score_i | X_i]$, quantile regression estimates the conditional quantile $Q_\tau[c_score_i | X_i]$ for quantile $\tau \in (0, 1)$:

$$Q_\tau(c_score_i | X_i) = X_i' \beta_\tau$$

where β_τ is the vector of quantile-specific coefficients obtained by minimising the asymmetrically weighted sum of absolute deviations. Comparing β_τ across $\tau = 0.10, 0.50$, and 0.90 reveals effect heterogeneity: whether the determinants of vulnerability operate with greater or lesser force for women at low, median, and high levels of vulnerability. If coefficient magnitudes increase with τ , this indicates that socioeconomic factors matter more for the most vulnerable women. This is a form of distributional heterogeneity not recoverable from OLS mean regression alone.

3.3.4 Oaxaca-Blinder Decomposition

An Oaxaca-Blinder decomposition (Blinder, 1973; Oaxaca, 1973) is applied to the urban-rural gap in mean AF vulnerability scores. Let μ_R and μ_U denote the mean AF score for rural (R) and urban (U) women, respectively. The raw gap ($\mu_R - \mu_U$) is decomposed as:

$$\mu_R - \mu_U = (\bar{X}_R - \bar{X}_U)' \beta_U + \bar{X}_R' (\beta_R - \beta_U)$$

The first term $(\bar{X}_R - \bar{X}_U)' \beta_U$ is the endowments component, attributable to differences in the mean levels of observed characteristics between rural and urban women (evaluated at urban returns). The second term $\bar{X}_R' (\beta_R - \beta_U)$ is the coefficients component, attributable to structural differences in the returns to those characteristics between the two groups. A significant endowments

component implies that equalising observable characteristics such as education and wealth would partially close the urban-rural gap. A significant coefficients component implies structural barriers potentially including infrastructure gaps, social norms, or labour market segmentation that persist beyond differences in observable endowments. The decomposition is estimated using the Stata `oaxaca` command with the `weight(1)` option (Neumark normalisation) and robust standard errors.

3.3.5 Domain-Specific Regressions

Five domain-specific OLS regressions are estimated, one for each binary deprivation indicator as the dependent variable, using the same control set as the primary OLS. This disaggregates the composite AF findings and reveals which socioeconomic factors drive which specific type of financial deprivation. These regressions are formally LPMs for binary outcomes but are labelled domain-specific OLS for consistency with the convention in this literature. Robust standard errors are applied.

3.3.6 Interaction Models

Two interaction models are estimated to test for effect heterogeneity. The first adds an Education $\times$ Residence interaction (`i.v106` $\times$ `i.v025`) to the primary OLS equation:

$$c_score_i = \alpha + \beta_1 Educ_i + \beta_2 Rural_i + \beta_3 (Educ_i \times Rural_i) + X_i' \gamma + \Sigma \gamma_s \cdot State_{si} + \varepsilon_i$$

This tests whether the estimated relationship between education and vulnerability differs between urban and rural women. Marginal predicted values at each education level, separately for urban and rural, are computed using Stata's `margins` command and plotted as Figure 8. The second interaction model adds a Wealth $\times$ Social Group interaction (`i.v190` $\times$ `i.social_group`) to test whether the vulnerability-reducing effect of wealth differs across caste-religion categories.

3.3.7 Intergenerational Analysis

Two outcome regressions examine intergenerational dimensions of vulnerability. The first regresses a child mortality rate defined as the proportion of children ever born who did not survive, $(v201 - v218)/v201$, computed for women with at least one live birth on the AF vulnerability score with the full control set and state fixed effects:

$$mortality_rate_i = \alpha + \delta \cdot c_score_i + X_i' \gamma + \Sigma \gamma_s \cdot State_{si} + \varepsilon_i$$

A positive and statistically significant coefficient δ provides evidence of intergenerational disadvantage transmission: financially vulnerable mothers are associated with higher rates of child mortality.

The second regression uses the son preference index — the share of living children who are male, v202/v218, for women with at least one living child — as the dependent variable. Both regressions use robust standard errors. The intergenerational analysis is interpreted as cross-sectional association rather than causal transmission, given the cross-sectional design of NFHS-5.

3.4 Software and Packages

All analyses are carried out in Stata 17 (StataCorp, 2021). We use the following user-written packages: `outreg2` (Wada, 2023) for regression table output, `estout/esttab` (Jann, 2023) for side-by-side model presentation, `coefplot` (Jann, 2014) for coefficient plots, `oaxaca` (Jann, 2008) for decomposition analysis, and `asdoc` (Shah, 2020) for direct Word export. Tables are generated with `asdoc` and `esttab`, and figures are exported as high-resolution PNG files.

4. Results and Discussion

4.1. An overview of Description Statistics and causes of Vulnerability:

The analytical foundation of this report begins with the central tendencies, variances, and distributional shape of the vulnerability metrics within the sample of 30,226 women. Table 1a shows that the average woman lacks nearly half of all possible financial needs, with an average score of 0.48 out of 1. More importantly, 83.17% of the women in this study fall into the "vulnerable" category. Further The mean AF vulnerability score (`c_score`) is 0.483 (SD = 0.212), and 83.17% of women in the analysis sample are classified as financially vulnerable (`c_score` $\geq$ 0.33, i.e., deprived in two or more dimensions). Figure 1 supports this with a bar chart showing most women are grouped around the 0.4, 0.6, and 0.8 marks. This shows a huge portion of the population is living in a fragile financial state, rather than just a small minority. This evidently supports the fact that vast majority of women are completely unequipped to handle sudden economic shocks, medical emergencies, or life transitions, keeping them dependent in India.

On the other hand, Tables 1b and table 2 drawn upon core Alkire-Foster model, breaks down exactly what the women lack, revealing the root causes of their financial fragility. Only 9.86% of the women lack a basic bank account, which sounds positive at first.

However, this hides the real problem: 77.56% do not have digital banking skills, 77.97% cannot access credit or loans, and 66.24% lack basic assets.

In India, while initiatives have successfully provided basic bank accounts, women face steeper financial learning curves and need specific support to execute digital transactions or understand the digital financial ecosystem.

Having a bank account is practically meaningless without digital literacy, because being part of the digital financial ecosystem creates digital trails that help financial service providers discover women and offer them access to affordable credit and insurance. As India pushes for greater financial inclusion, enabling women's participation in digital ecosystems like UPI is vital.

Furthermore, table 1c emphasises that the women in the study have an average age of 31 and live in households with about 5 members. The child mortality rate averages 0.034, but the data shows that when child deaths happen, they hit specific families very hard. There is also an average score of 0.475 for son preference, showing that cultural desires for male children are still common. This cultural preference often acts as a coping mechanism; because women lack a financial safety net of their own, they are forced to view male children as their only long-term financial security.

4.2.The Paradox of Wealth, Education, and Social Identity:

The research further took shape when C_score was generated for various socio-economic dynamics to calculate the mean variability score as mentioned in Table 3 and Figure 3. It shows that wealth alone does not neatly fix vulnerability. The poorest women have the highest vulnerability score (0.496). However, middle-income (0.482) and richer women (0.484) score slightly worse than the "poorer" group (0.480). Figure 4 shows a similar pattern for education: vulnerability increases from women with no education (0.479) to those with primary (0.491) and secondary education (0.495). It only drops sharply for women who finish higher education (0.453). The cause of this paradox is rooted in traditional gender roles. Women in the poorest groups often must work menial jobs to survive, giving them a small degree of cash interaction. As families gain wealth, they often enforce stricter rules keeping women at home, making them more dependent. The narrative only changes with higher education. Contemporary research shows that education is a primary pathway to empowerment, directly increasing a woman's chances of joining the workforce, earning better wages, and having more say in family financial matters.

Similarly, upon understanding the inherent social structure of India and tried quantifying social factors such as caste, religion and social groups, it evident in Table 3 that even social identity and religion strongly affect a woman's financial independence.

Tribal groups (ST) have the lowest, most secure vulnerability score (0.451). General Hindu women, despite often having more social status, score worse (0.498). General Muslim women face the highest burden with a score of 0.515. The primary cause of this disparity lies in differing social structures. Lower family incomes and strict cultural constraints often force young women in certain minority communities to prioritize household duties over education, leading to high dropout rates and prolonged financial dependence. Conversely, tribal communities historically maintain more egalitarian rules regarding female labor, allowing those women to achieve greater financial resilience.

Figure 5 maps this out geographically, showing that where a woman lives matters greatly. Living in Manipur adds 0.157 to the vulnerability score, while living in Arunachal Pradesh subtracts 0.103. This geographic split emphasizes that local culture, infrastructure, and state-level policies play massive roles in a woman's financial independence.

4.3.Methodological Integrity and Data Robustness

To establish further relationship between factors, principal component analysis was conducted. Table 5 uses math to group the different types of financial lack. Figure 2 is a line chart showing a sharp drop after the first group. The math proves that having a bank account is separate from having digital skills or having access to credit. Measuring financial health by looking at bank accounts alone is a mistake; the multidimensional method used here is vital because it conceives of poverty and vulnerability as an experience of overlapping deprivations, proving that focusing on simple monetary or single-issue metrics fails to capture a person's true lived reality.

To ensure these findings are accurate, the primary scoring method was tested against a secondary mathematical model. Table 4 finds a strong positive link (a 0.768 correlation) between the two. Figure 6 plots these scores on a graph, and the dots form a tight line. Table 8 shows that the two different models agree 83.17% of the time. This high agreement proves the study's way of measuring who is disadvantaged is highly reliable. Table 6 shows the study narrowed a massive national dataset down to 26,899 women who answered every single question, ensuring no missing data errors. Tables 7a and 7b confirm the statistical models are stable. Table A proves that higher education lowers vulnerability across all five financial categories (like digital, credit, and assets), confirming it is a universal fix. Table B re-runs the math to represent the entire national population, confirming that the patterns of vulnerability discussed here are a nationwide reality, not just an isolated sample.

4.4. Structural Drivers and Intergenerational Consequences

Moreover, to understand the main causes of vulnerability, Table 9 and Table 10 look at what specific life events and traits cause vulnerability. Figure 7 plots the results side-by-side to show they match. The data shows that higher education drops a woman's vulnerability score by 0.054 points. Having a job drops the score by 0.046 points, which provides more protection than simply living in the richest household group. A major consequence highlighted here is the "widowhood penalty": widows and divorced women see their vulnerability score go up by 0.026. Because they were reliant on a male provider, the loss of that relationship plunges them directly into financial darkness. Further, Table 12 looks at women at the very top and bottom levels of hardship. It shows that the benefits of education and jobs are much bigger for the most deprived women.

For women who are already doing well, higher education drops their score by 0.040. But for the most deprived women, higher education drops their score by a massive 0.107 points. Figure 8 plots this out, showing that higher education acts as a great equalizer, dramatically closing the vulnerability gap between women living in cities and those living in rural areas.

Similarly, Table 11 reveals the most tragic consequence of financial exclusion: a mother's financial struggles directly impact the survival of her children. For every 1-point increase in a mother's vulnerability score, the rate of child deaths in her home goes up by 0.041. Figure 9 shows this visually: as the vulnerability score moves toward 1 (total lack), the line for child mortality climbs steeply.

When mothers lack financial autonomy and basic savings, they cannot afford out-of-pocket healthcare expenses or adequate nutrition for their children. Severe malnutrition and maternal anaemia act as silent multipliers that weaken a child's immunity, increasing their vulnerability to preventable diseases. An estimated 4.9 million children globally died before their fifth birthday in 2024, but most of these deaths are entirely preventable with access to quality health care and low-cost interventions. Equipping women with financial capability is quite literally a life-saving measure. Furthermore, the table shows that higher financial vulnerability increases a mother's preference for having sons by 0.024 points, perpetuating a cycle where women must rely on male offspring rather than financial institutions for their future security.

5. Policy Implications:

The constructed MFVI index shows compelling need to formulate more robust policies to attain better and genuine financial inclusion. Though existing policies such as Sukanya Samridhi Yojana,

Pradhan Mantri Mudra Yojana etc, can be seen as a proactive steps taken by government for financial inclusion, the revelations of study, suggest for a more robust and multidimensional policy formulation for attaining financial inclusion.

5.1 Expanding Beyond Account Access: Digital and Credit Dimensions

The most alarming finding from the MFVI analysis is that digital financial deprivation (77.57%) and credit deprivation (77.97%) dwarf bank account deprivation (9.86%). This reveals a fundamental gap in India's financial inclusion architecture: while the Jan Dhan Yojana has successfully opened millions of bank accounts, it has not ensured that these accounts are actively used for digital transactions, credit, or savings. Policy must now pivot from account opening to account activation, financial deepening and by further strengthening by basic financial and digital literacy programme specifically targeting rural women would be more effective in reaching those most deprived.

5.2 Employment opportunities:

The regression results consistently show that employment is the most powerful individual-level protective factor against financial vulnerability. This makes women's labour force participation a priority policy lever. The PM Employment Generation Programme (PMEGP) provides subsidised loans for self-employment and could be expanded to include financial literacy components. The DAY-NRLM, which already reaches millions of women through SHGs, should be strengthened with livelihood components that link women directly to formal employment opportunities.

State-level monthly income support schemes such as the Mukhyamantri Majhi Ladki Bahin Yojana in Maharashtra (₹1,500 per month), the Subhadra Yojana in Odisha, and pengal urimai thogai in Tamil Nadu(₹ 1500 per month) provide a short-term income floor for vulnerable women. While welcome, these should be complemented by graduation programmes that help women transition from cash transfers to sustainable employment and asset ownership.

5.3 Asset Ownership and Long-term Security

Asset deprivation (66.24%) is the third most prevalent form of financial vulnerability in the MFVI. The Pradhan Mantri Awas Yojana (PMAY) already requires that houses constructed under the scheme be registered in women's names or as joint ownership, which is a significant step. Expanding this principle to agricultural land where women's land rights remain insecure in most states would directly reduce the asset dimension of the MFVI.

5.4 Targeting the Most Deprived: Intersectional Interventions

The quantile regression results show that the effects of education and employment are largest among the most deprived women those at the 90th percentile of the vulnerability distribution. This argues for targeted interventions that identify the most multiply deprived women and provide bundled support: digital access, credit, employment linkages, and savings facilitation simultaneously, not sequentially. The New Swarnima Scheme (loans up to ₹2 lakh for backward-class women) and the Mahila Samridhi Yojana (microfinance via SHGs) are examples of targeted instruments that could be scaled.

The finding that Muslim women face the highest mean vulnerability scores (0.515) suggests that cultural and community-level barriers not just economic factors must be addressed. Programmes that work through trusted local intermediaries (community women leaders, religious community organisations) may be more effective than top-down schemes in reaching this group.

5.5 Intergenerational Policies: Investing in Children through Mothers

The finding that higher MFVI scores are associated with higher child mortality rates even after controlling for maternal education, wealth, and state fixed effects provides a powerful justification for financial vulnerability reduction as a child health policy. The Pradhan Mantri Matru Vandana Yojana (PMMVY), which provides ₹5,000–₹6,000 to pregnant and lactating women, and the Janani Suraksha Yojana (JSY), which incentivises institutional deliveries, are directly relevant. Extending PMMVY coverage and linking it to ongoing financial inclusion milestones (such as regular savings or credit access) could simultaneously reduce maternal financial vulnerability and improve birth outcomes.

Thus, the policy response to multidimensional financial vulnerability among Indian women must be multi-faceted, targeted, and intergenerational. No single scheme will resolve deprivation a coordinated national framework modelled on that explicitly measures and monitors all five dimensions of the MFVI can solve for it in near future.

6. Limitations

6.1 Cross-Sectional Design and Causality

The NFHS-5 is cross-sectional, meaning the study identifies statistical associations rather than causal relationships. All regression coefficients are interpreted as conditional associations, not causal effects. The direction of causality between employment status and financial vulnerability, for instance, is theoretically ambiguous: employment may reduce vulnerability through income,

but vulnerability may simultaneously constrain women's ability to enter formal employment. Panel data or natural experimental designs would be required to recover causal estimates.

6.2 Sample Attrition and Selection Bias

The financial inclusion module was administered selectively, reducing the complete-case analytic sample from 724,115 to approximately 30,226. If selected households differ systematically from those not selected, estimates may not be fully representative of the population. The survey-weighted robustness check (Table B) partially addresses this concern, and the near-identical weighted and unweighted estimates suggest selection bias is not severe.

6.3 Measurement Constraints of the AF Index

The five dimensions reflect data availability in NFHS-5 rather than a theoretically complete account of financial vulnerability. Insurance coverage, pension access, and informal safety nets prominent in the theoretical literature are not captured. The equal-weighting convention is normative; the PCA-weighted robustness check confirms that within this dimension set, the weighting choice does not materially affect findings.

6.4 The Counterintuitive Education and Wealth Effects

The positive association between education and AF vulnerability score, and between higher wealth quintiles and AF scores, reflects a measurement mechanism rather than genuine increases in insecurity: more educated and wealthier women participate more actively in formal financial systems and therefore register more account-based deprivations. This does not imply education or wealth increases genuine financial insecurity.

6.5 Temporal Scope and COVID-19

The NFHS-5 was collected between 2019 and 2021, overlapping with the early COVID-19 pandemic phase. The pandemic disrupted labour markets and financial behaviours in ways that may not represent longer-run structural conditions. Without comparable pre-pandemic data at the same scale, the extent to which findings reflect pandemic-specific disruptions versus enduring structural vulnerability cannot be fully assessed.

7. Conclusion

In conclusion, this paper has constructed and analysed a Multidimensional Financial Vulnerability Index (MFVI) for women aged 15–49 in India using NFHS-5 data. Using the Alkire-Foster dual-cutoff method, the MFVI measures simultaneous deprivation across five dimensions: bank account access, digital financial services, asset ownership, credit access, and savings behaviour, each weighted equally at 0.20.

The important findings are as follows. First, deprivation in digital financial services (77.57%) and credit access (77.97%) is overtly more common than deprivation in bank account access (9.86%), revealing a structural gap between formal account ownership and financial inclusion. Second, employment is the most powerful protective factor against financial vulnerability, followed by newspaper readership, higher education, and rural residence. Third, the effects of these protective factors are substantially larger roughly 50% larger among the most deprived women (those at the 90th percentile of the vulnerability distribution), suggesting that general-purpose policies are also the most progressive. Fourth, maternal financial vulnerability is positively associated with child mortality rates, even after controlling for a rich set of confounders, underscoring the intergenerational consequences of financial deprivation.

These findings reaffirm the importance of multidimensional approaches to understanding and addressing financial vulnerability. A woman with a bank account but no credit, no savings, and no digital access cannot be considered as financial inclusion. Effective policy must therefore address all dimensions simultaneously and must be targeted at the most deprived groups.

This paper further contributes to the growing literature on multidimensional vulnerability in India but is subject to several limitations. The analysis sample is a subset of the full NFHS-5 survey, and the cross-sectional nature of the data limits causal inferenc
